

**Table 9: infections by protozoans** (single-celled animals)

Disease	Pathogenic agent	Infectious for / observed in:		Symptoms	Detection / identification	Treatment	Source of infection / Prevention	
		lorisinae	other prosimians					Simians, humans; primates in general; other species
Amebiasis	<i>Entamoeba histolytica</i> ( <i>Entamoeba coli</i> : nicht pathogen)	"All primates" <sup>3</sup>	Lemurs <sup>1</sup> , "all primates" <sup>2,3</sup>	"All primates" <sup>3</sup> , may be fatal for humans <sup>2</sup> ; less infectious for monkeys and apes. Latent infection possible <sup>3</sup>	Without clinical symptoms or dysentery <sup>1</sup> , flatulence (inflation of the intestine), exsiccosis (loss of water), thirst <sup>4</sup> , severe depression <sup>2</sup> , gut ulceration <sup>3</sup> , enlarged liver <sup>2</sup> , hepatic abscesses <sup>3</sup> , death within 4 weeks <sup>2</sup>	in faeces (may be present without being pathogenous) <sup>1</sup> microscopically on warm! material or in histology of gut-content.	<i>Metronidazol</i> ; 10 mg/kg <i>Carnidazol</i> * for three days <sup>1</sup> ; <i>Diiodohydroxyquin</i> , 20 mg / kg twice per day for for three weeks <sup>3</sup> , <i>Clont</i>	Usually in faeces <sup>1,3</sup> ; water, salad and fruits should be washed <sup>1</sup>
Balantidiasis	<i>Balantidium coli</i>	"All primates" <sup>2</sup>	"all primates" <sup>2</sup>	Common in chimpanzees, present in many species <sup>3</sup> , dangerous for humans <sup>2</sup>	Ulcerative enteritis (inflammation of the intestine), colitis with abundant mucus, but seldom bloody <sup>2</sup> ; severe dysentery in humans, usually has little effect on nonhuman primates <sup>3</sup>	In faeces (may be present without being pathogenous) <sup>2</sup> ; microscopically on warm! material or in histology of gut-content should be distinguished from <i>Entamoeba coli</i>	<i>Diiodohydroxyquin</i> , 20 mg / kg twice per day for for three weeks <sup>3</sup> , <i>Clont</i>	
Toxoplasmosis	<i>Toxoplasma gondii</i>	In slow-loris	In ring-tailed lemur, ruffed lemur. "In prosimians" <sup>1</sup> , dangerous for lemurs, especially for <i>L. catta</i> <sup>1</sup>	In many species of new world monkeys <sup>3</sup> ; some old world monkeys, less infectious for simians than for lemurs <sup>1</sup>	Symptoms mostly unspecific or abortion or pulmonal / neurological symptoms possible. In lemurs: reduced food consumption, sometimes diarrhoea, lethargy, hypothermia, lack of coordination, abnormal movements, ascites, liquid in thorax or pericard, liver degeneration, necroses in liver, kidney, spleen, death after 2-12 days <sup>1</sup>	Serological examination in intervals of 10-14 days (increasing antibody titer) <sup>2</sup> Histologically on post-mortem material <sup>1</sup>	Treatment difficult; usually fatal in spite of use of antibiotics; success in two cases with <i>Maderan</i> <sup>R</sup> for children ( <i>Sulfadiazin</i> , <i>Pyromethamine</i> ) for 16 days plus vitamins ( <i>Protovit</i> ®) <sup>1</sup>	ZOONOSIS! Transmission diaplacental or oral. From faeces of cats.
Trichomoniasis	<i>Trichomonas</i> sp. <sup>61</sup> (for example <i>Tritichomonas gastritis</i> )	In <i>Nycticebus coucang</i> (n=2) <sup>61</sup>		In non-human primates like rhesus macaques, humans, birds	<i>N. coucang</i> : one of two infected animals had bloody stool and diarrhea. It is not known whether trichomonads were the cause of the bloody stool, but the condition improved with treatment <sup>61</sup> In non-human primates either gastritis, vaginitis ( <i>T. vaginalis</i> ); in humans pneumonia ( <i>T. tenax</i> , <i>T. hominis</i> )	Microscopically or in necropsy. <i>N. coucang</i> : found in faeces (n=2) <sup>61</sup> .	In humans: <i>Metronidazol</i>	Common in birds
	<i>Giardia</i> sp.	In <i>Nycticebus pygmaeus</i> (n=3), <i>N. coucang</i> (n=3) <sup>61</sup>	Occasionally in lemurs ( <i>L. catta</i> , <i>E. mongoz</i> ) <sup>1</sup>		Bloody diarrhoe, sometimes vomiting <sup>1</sup>	In faeces <sup>1,61</sup>	<i>Metronidazol</i> ; 10 mg/kg <i>Carnidazol</i> for three days <sup>1</sup> ( <i>Carnidazol</i> : very bad taste for primates; 10 % of substance mixed with calcium carbonate, added to the food. <sup>2</sup> )	Direct infection; no other host necessary <sup>1</sup>

**Table 9: infections by protozoans** (single-celled animals)

Disease	Pathogenic agent	Infectious for / observed in:		Symptoms	Detection / identification	Treatment	Source of infection / Prevention	
		lorisinae	other prosimians					Simians, humans; primates in general; other species
	<i>Blastocystis hominis</i>	In <i>Loris</i> <sup>15</sup> ; Mehlhorn, pers. comm.)		In a variety of hosts <sup>7</sup>	Regarded as not pathogenous for a long time; but can, for unknown reasons, suddenly become pathogenous, then multiplies considerably and penetrate the intestinal villi. Symptoms: severe diarrhoea, severe exsiccosis (loss of water) <sup>7</sup> . In <i>Loris</i> : wet fur all over the body (especially in juveniles) or only slightly clotted hair in the surroundings of the anal region; behaviour vivid, normal. In some animals thirst <sup>15</sup> .	In faeces: size of stages 5-30 µm, containing a large nucleus which cannot be stained with iodine; crescent-shaped chromatin at the rim. Between intestinal villi: size of stages 50-150 µm, food vacuoles included <sup>7</sup>	<i>Metronidazol</i> (Mehl-horn, pers. comm.). In <i>Loris</i> : <i>Metronidazol</i> , dissolved in water and added to the daily milk pap, was readily eaten; symptoms vanished within 5 days <sup>15</sup> .	Apparently oral infection from faeces (dirty food) <sup>7</sup>
Cryptosporidiosis	<i>Cryptosporidium</i> sp. ( <i>C. parvum</i> ?)	In <i>Loris</i> , n=1, one fatal opportunistic infection in an old animal (Mehlhorn, pers. comm.); primary cause of death was renal failure <sup>15</sup> . In captive <i>Nycticebus coucang</i> <sup>61</sup>		<i>C. parvum</i> in a variety of hosts <sup>4</sup> . Deaths in humans, especially in cases of immunodeficiencies such as AIDS <sup>4, 5, 16</sup> , Mehlhorn, pers. comm.) In experimentally SIV infected rhesus monkeys.	Infections most frequent in juveniles and in cases of immunodeficiency (see HIV, SIV); secondary infection due to disease from other pathogenic agents which influence the immune system. Symptoms: gastroenteritis, diarrhoea, severe exsiccosis, indigestion, loss of weight, sometimes colic, disturbance of motility. <sup>4</sup> . Abdominal seizures <sup>16</sup> . In <i>Loris</i> : symptoms of excitement, reduced food consumption, increasing weakness, death. No increase of thirst observed (n=1, old specimen) <sup>15</sup> . Severe inflammation of liver and gall bladder <sup>63</sup>	Detection of <i>oocysts</i> in faeces <sup>4</sup> ; histologically: pathogenic agents visible (dark spots), fixed to the intestinal epithelium <sup>16</sup> or the epithelium of the gall bladder	In humans: no chemotherapy known; typical medicine against Coccidiosis and amoeba ineffective (Mehlhorn, pers. comm., <sup>16</sup> ). For domestic animals: <i>Lasalocid</i> (for calves 15 mg/kg, for lambs 5 mg/kg for 3 days), in addition electrolyte solution for replacing the water; <i>Buscopan</i> against colic, if necessary <sup>4</sup>	Common; mainly oral infection from faeces of infected calves. Sick animals emit larger quantities of <i>oocysts</i> , especially in the middle of the 14-day-period of disease; in sufficient humidity these remain infectious for 6 months. Prevention by removal of faeces, cleaning with hot steam, disinfection for instance with Lysococ <sup>4, 16</sup>
